Super Trace Analysis

Improved detection limits for Key Pathfinders.

Continued improvement in instrumentation and sample introduction systems providing the lowest Detection Limits in the industry for near-total four acid and partial digestion methods.

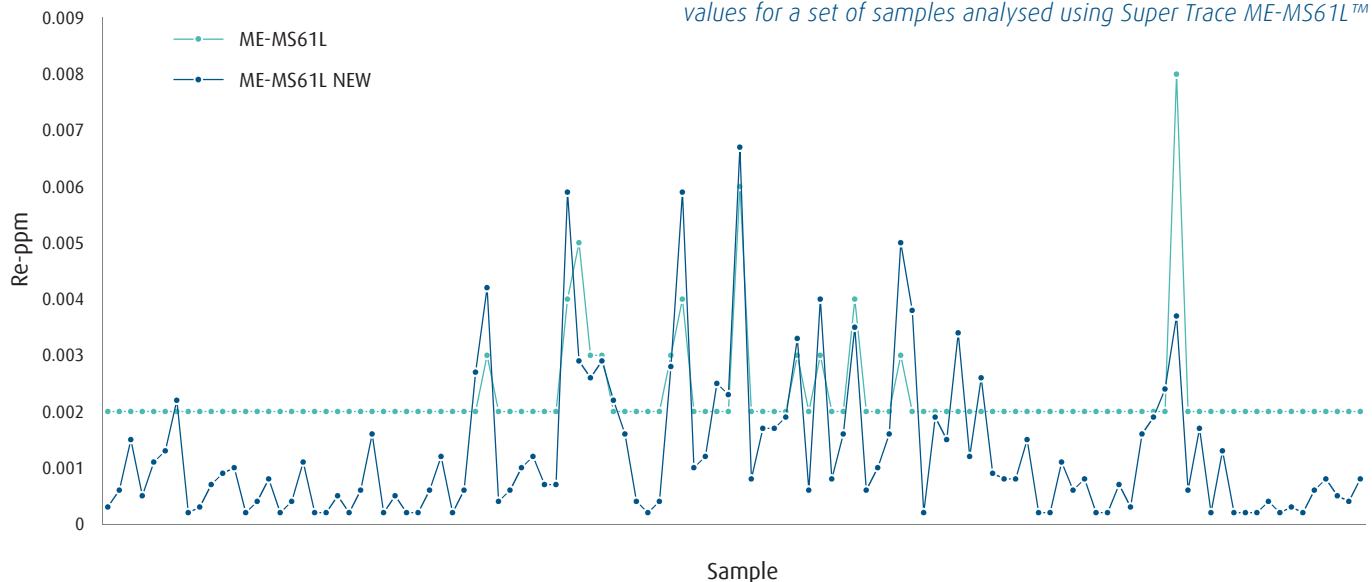

ALS continues to improve detection limits in our industry leading super trace ICP-MS methods. Both the four acid and aqua regia digestion methods have reduced detection limits for key elements of interest to exploration geologists as shown in the adjacent table.

The precision of a measurement depends on detection limit, the method's precision expectation, and concentration of the result. The improvements ALS has made in ICP-MS methodologies mean that not only are much lower detection limits achieved, but the exploration geochemist also has a much greater degree of confidence in the separation of anomaly from background, giving confidence in subtle anomalies in sampling programs.

Improved Detection Limits

	Analyte	Previous LDL ppm	New LDL ppm	Improvement factor
4-Acid	As	0.05	0.02	2.5
	Bi	0.005	0.002	2.5
	Re	0.002	0.0004	5
	Se	0.2	0.006	33.33
	Te	0.04	0.005	8
	Tl	0.004	0.001	4
Aqua Regia	Bi	0.001	0.0005	2
	Re	0.001	0.0002	5
	Se	0.1	0.003	33.33
	Te	0.01	0.003	3.33
	Tl	0.002	0.001	2

Increased separation for Re with a much greater Re anomaly to background values for a set of samples analysed using Super Trace ME-MS61L™

The lower DL's produce data sets with a substantially lower proportion of results below detection and decrease the effect of binning at lower concentrations. The proportion of the Re results above detection, in this case improved from 25% to nearly 90%, and the binning of low values was substantially reduced. The latest reduction in detection limits for Re, Te and Se have pushed the DL's below the upper crustal abundance for these elements.

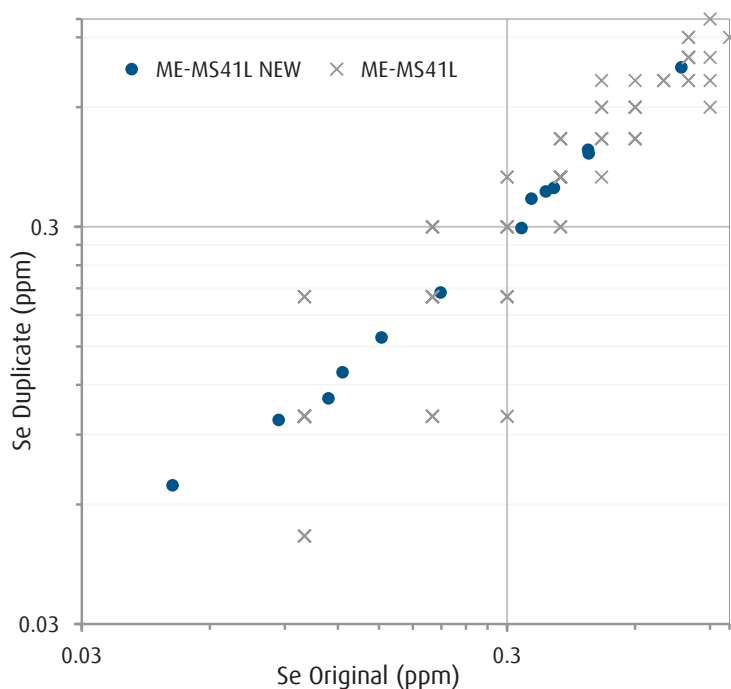

Our new super trace packages provide robust results at levels well below the lowest regional backgrounds for most elements; allowing an unprecedented level of detail in major and trace element geochemistry on every sample. Importantly, detection limits are below regional background for key pathfinders like Tl, Sb, Te, Cd, Se, Re, and As, allowing clear definition of anomalous patterns and trends.

Leading the field in analytical innovation

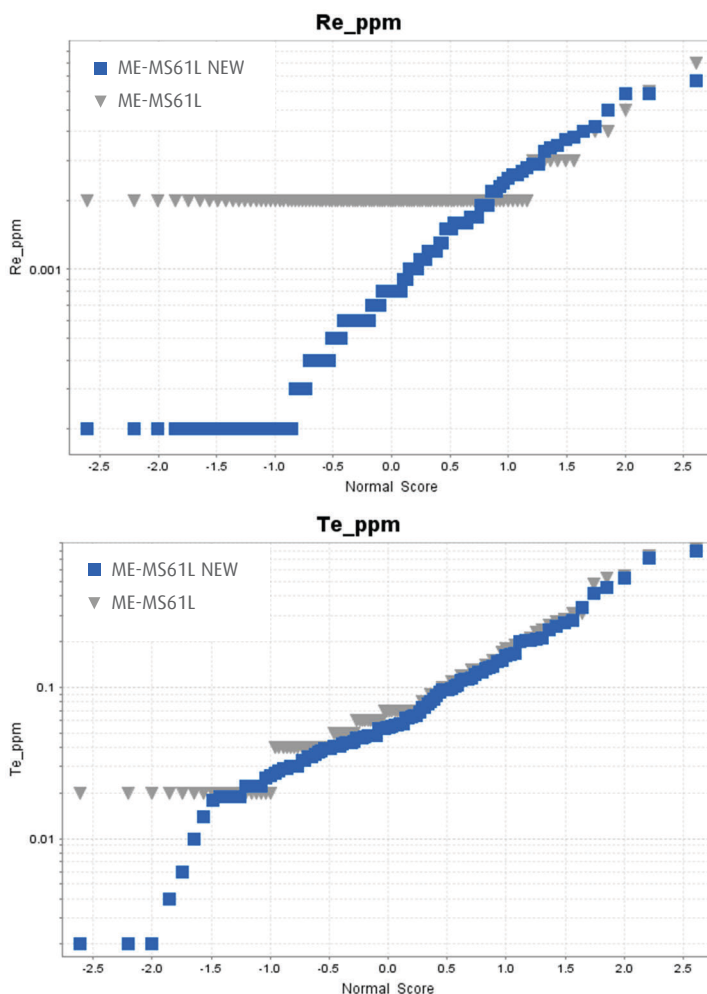

The expert method development team at ALS have achieved unrivaled detection limits with an advanced sample introduction system designed in-house. Benefits of this technology include higher signal to noise ratios, fewer oxide and polyatomic interferences, and low carry over effects. A major source of uncertainty in ICP-MS analysis is the formation of oxides in the plasma. The super trace methodology at ALS results in oxide formation of <0.5%, compared to ~3% achieved with other instrumentation.

In other words, the usual problems preventing ultra-low detection limits in ICP-MS analysis of geological materials are minimized, allowing a greater separation of geochemical anomaly from background and the ability to more finely detail changes in alteration and lithology using multivariate analysis.

Increased confidence of exploration geochemical data at low concentrations with improved precision of low-level Se in sample duplicates.

Data set of ME-MS61L™ analysed with both the previous and new detection limits for Re and Te.

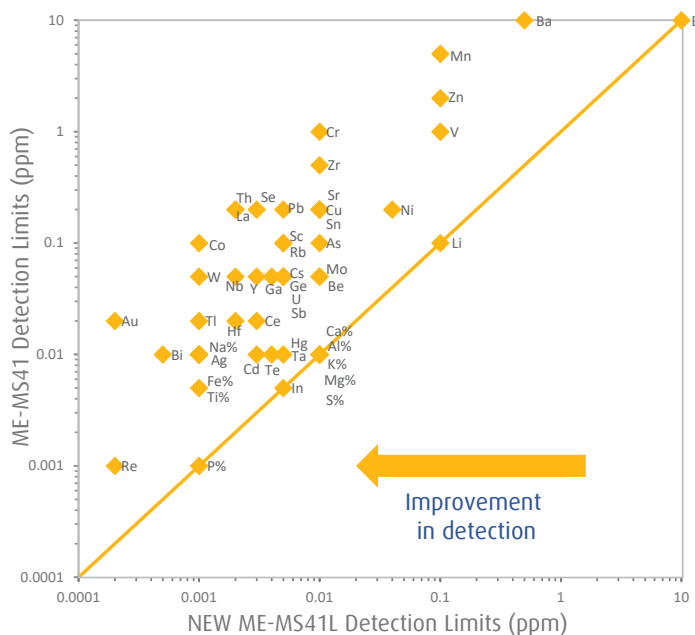

Super Trace 53 Elements by Aqua Regia and ICP-MS/ICP-AES

The Super Trace method is available for samples processed using our standard aqua regia digestion (ME-MS41L™) or with our weak acid digestion (ME-MS41W™).

Both digestions are available for standard soils and sediments, as well as with our clay separation technique. The Super Trace method has been optimized for long-term ICP-MS signal stability, in particular for samples with very high Ca content.

These partial digestion methods are useful for identifying anomalism through cover and in regional programs as mineral coatings are preferentially dissolved while “diluting” silicate minerals remain undissolved.

Super Trace 48 elements by four acid digestion and ICP-MS / ICP-AES

Four acid multi-element analysis is an effective tool in mineral exploration because of its ability to provide a full pathfinder element suite as well as a cost-effective proxy for mineralogy.

In addition to the traditional mapping of base metal and trace element anomalies, major element results across an entire drill program can be used in lithogeochemical modeling when combined with standard whole rock analysis techniques on a smaller sample set. Similarly, ME-MS61L™ can be used for bedrock lithomapping in residual soils. The information gained from near-total multi-element analysis adds value to minerals projects well beyond exploration and into geometallurgy and environmental planning.

The four acid digestion dissolves nearly all minerals in the majority of geological samples. The rare earth elements, which are not fully extracted in a four-acid digestion, may be added to this package on request. Mercury must be analyzed separately.

ALS METHOD CODE	DESCRIPTION
ME-MS41L™	Standard ALS aqua regia digestion, paired with new ICP-MS technologies that provide super-trace detection limits on key pathfinder elements. Directly comparable to bulk soils analyzed with the same method.
ME-MS41W™	Weak acid leach using 1:1 ratio of nitric and hydrochloric acids, paired with new ICP-MS technologies that provide super-trace detection limits on key pathfinder elements. Designed to minimize background signal and cause geochemical anomalies in weakly-bound ions to stand out.
ME-MS61L™	HNO ₃ -HClO ₄ -HF acid digestion, HCl leach, dissolves nearly all minerals in the majority of geological samples, paired with ICP-MS and ICP-AES analysis provide super-trace detection limits.

ALS provides a wide range of specialised testing services covering all stages of your project's life cycle.
